1. Introduction

In this paper, we study robust stabilization by a stable controller for a single-input single-output infinite dimensional system. The advantage of stable controllers is well appreciated in that such controllers are robust against a sensor or actuator failure [1] and the saturation of the control input [2]. Typical examples are flexible structures [3] and traffic networks [2]. Additionally, stable controllers are preferred for control of electromechanical positioning devices [4]. We also recall that two plants are simultaneously stabilizable if and only if an associated plant derived from these two plants is stabilizable by a stable controller [5].

For finite dimensional systems, several design methods of stable $\mathcal{H}_\infty$ controllers have been developed: linear matrix inequalities or algebraic Riccati equations [6,7] and non-smooth, non-convex optimization [8]. On the other hand, for infinite dimensional systems, while sensitivity reduction by a stable controller has been studied in [9–11], robust stabilization by a stable controller still remains to be an open problem.

Let us briefly summarize the difference between these two problems. Sensitivity reduction by a stable controller can be transformed to the modified Nevanlinna–Pick interpolation [9,12–14], and the associated $\mathcal{H}_\infty$-norm condition is $\|F\|_\infty < \rho$, where $F$ is a solution of the unit interpolation problem. On the other hand, in robust stabilization by a stable controller, the counterpart is $\|W - mF\|_\infty < \rho$, where $W = 1/W \in \mathcal{H}_\infty$ and $m \in \mathcal{H}_\infty$ is inner. Since $F$ needs to be a unit element, we cannot change this norm condition to a simpler one, although we can in the usual robust stabilization problem. We overcome this difficulty by extending the technique of [14]. We will discuss this technique in Section 3.

This paper studies a class of plants having finitely many simple unstable zeros but possibly infinitely many unstable poles. An example of such plants is a system with delayed feedback such as repetitive control systems [15,16]. The objective of the present paper is to obtain lower and upper bounds on the multiplicative perturbation under which the plant can be stabilized by a stable controller. In addition, we find stable controllers to provide robust stability. We also present a numerical example to illustrate the results and apply the proposed method to a repetitive control system.

Notation and definitions

Let $C_+$ denote the open right half-plane $\{s \in C \mid \text{Re}s > 0\}$. For $s \in C \setminus \{0\}$, the principal value $\text{Log} s$ is the complex logarithm whose imaginary part lies in the interval $(-\pi, \pi]$. 
The space $\mathcal{H}^\infty$ denotes the Hardy space of functions that are bounded and analytic in $\mathbb{C}_+$, and $\mathcal{RH}^\infty$ denotes the subset of $\mathcal{H}^\infty$ consisting of real-rational functions. $U \in \mathcal{H}^\infty$ is called a unit element in $\mathcal{H}^\infty$ if $1/U \in \mathcal{H}^\infty$. For $G \in \mathcal{H}^\infty$, the $\mathcal{H}^\infty$ norm is defined as $\|G\|_\infty := \sup_{s \in \mathbb{C}_+} |G(s)|$. The field of fractions of $\mathcal{H}^\infty$ is denoted by $\mathcal{F}^\infty$.

Two functions $N, D \in \mathcal{H}^\infty$ are strongly coprime in the sense of [17] if $NX + DY = 1$ for some $X, Y \in \mathcal{H}^\infty$. By the corona theorem [5], $N$ and $D$ are strongly coprime if and only if there exists $\delta > 0$ such that $|N(s)| + |D(s)| \geq \delta$ for all $s \in \mathbb{C}_+$.

To denote the interpolation data $G(s_i) = \alpha_i (i = 1, \ldots, n)$ for $G \in \mathcal{H}^\infty$, we use the notation $(s_i; \alpha_i)_{i=1}^n$.

2. Problem statement

Consider the linear, continuous-time, time-invariant, single-input single-output closed-loop system given in Fig. 1. Let the plant $P$ and the controller $C$ belong to $\mathcal{F}^\infty$. $P$ is said to be stabilizable if there exists $C$ such that $S := 1/(1 + PC)$, $CS$, and $PS$ belong to $\mathcal{H}^\infty$. For a given $P$, the set of all $C$ leading to $S$, $CS$, and $PS$ belong to $\mathcal{H}^\infty$ is denoted by $\mathcal{E}(P)$. $P$ is strongly stabilizable if $\mathcal{H}^\infty \cap \mathcal{E}(P) \neq \emptyset$.

Consider Problem 2.3. Let Assumptions 2.1 and 2.2 hold. Suppose $\rho > 0$. Determine whether there exists a controller $C \in \mathcal{H}^\infty \cap \mathcal{E}(P)$ satisfying (2). Also, if one exists, find such a controller $C$.

We call Problem 2.3 strong and robust stabilization. Our aim is to provide both a sufficient and a necessary condition for strong and robust stabilization. These conditions give lower and upper bounds on the multiplicative perturbation.

3. Strong and robust stabilization

In this section, we first transform Problem 2.3 to the problem of an interpolation–minimization by a unit element in $\mathcal{H}^\infty$. Next we obtain a sufficient condition as well as a necessary condition for the interpolation–minimization problem using the modified Nevanlinna–Pick interpolation [22].

Lemma 3.1 below is a scalar version of Lemma III.1 of [11]. This result provides a necessary and sufficient condition that a controller strongly stabilizes the plant. The next statement is different from that of Lemma III.1 in [11], but the modification is easy. So we omit the proof.

Lemma 3.1 ([11]), Suppose $P = N/D$, where $N, D \in \mathcal{H}^\infty$ are strongly coprime. Then $C$ strongly stabilizes $P$ if and only if $C, 1/(D + NC) \in \mathcal{H}^\infty$.

The following result shows that Problem 2.3 can be reduced to an interpolation–minimization by a unit element.

Theorem 3.2. Consider Problem 2.3 under Assumptions 2.1 and 2.2. Problem 2.3 is solvable if and only if there exists a function $F$ such that

\[ F, 1/F \in \mathcal{H}^\infty, \]
\[ \|W - M_0F\|_\infty \leq \rho, \]
\[ F(z_i) = \frac{W(z_i)}{M_0(z_i)}, \quad i = 1, \ldots, n. \]

Furthermore, once such a function $F$ is constructed, the solution of Problem 2.3 is given by

\[ C = \frac{W - M_0F}{M_0N_0F}. \]

Proof (Necessity). Let $C$ be a solution of Problem 2.3. Define $F := W/(M_0 + N_0C)$. Then $F$ satisfies (3) by Lemma 3.1. Since

\[ WT = W \left( 1 - \frac{M_0F}{W} \right) = W - M_0F, \]

$F$ also achieves the norm constraint (4). In addition,

\[ F(z_i) = \frac{W(z_i)}{M_0(z_i) + M_0(z_i)N_0(z_i)C(z_i)} = \frac{W(z_i)}{M_0(z_i)}, \quad i = 1, \ldots, n. \]

Thus $F$ satisfies (3)–(5).

(Sufficiency). Suppose $F$ satisfies (3)–(5), and define $C$ by (6). We show $C \in \mathcal{H}^\infty$ as follows. Since $1/N_0, 1/F \in \mathcal{H}^\infty$, it follows from (6) that

\[ M_0C = \frac{W - M_0F}{N_0F} \in \mathcal{H}^\infty. \]

Suppose $C \notin \mathcal{H}^\infty$. Then the unstable poles of $C$ must be the zeros of $M_0$ by (8). Let $z_i$ be such a pole. Since the zeros of $M_0$ are simple,
it follows that \((M_N C)(z_i) \neq 0\). In addition, since the units \(N_0\) and \(F\) do not have unstable zeros, \(N_0(z_i) \neq 0\) and \(F(z_i) \neq 0\). Hence

\[ W(z_i) - M_d(z_i)F(z_i) = (M_N C)(z_i) \cdot N_0(z_i)F(z_i) \neq 0, \]

which contradicts (5). Thus \(C\) belongs to \(\mathcal{H}^\infty\).

Moreover since

\[ \frac{1}{M_d + M_N C} \in \mathcal{H}^\infty, \]

\(C\) strongly stabilizes \(P\) by Lemma 3.1. \(C\) also achieves the norm constraint (2) by (4) and (7). Thus \(C\) is a solution of Problem 2.3. \(\square\)

We obtain a sufficient condition as well as a necessary condition for robust stabilizability by a stable controller using the following problem:

**Problem 3.3** ([22,23]). Suppose \(s_1, \ldots, s_n \in \mathbb{C}_+\) are distinct, and let \(\beta_1, \ldots, \beta_n \in \mathbb{C} \setminus \{0\}\). Determine whether there exists a function \(G\) such that \(G, 1/G \in \mathcal{H}^\infty, \|G\|_{\infty} \leq 1\), and \(G(s_i) = \beta_i\) for \(i = 1, \ldots, n\). Also, if one exists, find such a function \(G\).

**Problem 3.3** is called the modified Nevanlinna–Pick interpolation problem [22].

The difference between Problem 3.3 and the Nevanlinna–Pick interpolation problem [121] is that Problem 3.3 has the condition \(1/G \in \mathcal{H}^\infty\). Despite this difference, the solvability of Problem 3.3 is also equivalent to the positive semi-definiteness of an associated Pick matrix.

**Theorem 3.4** ([22,23]). Consider Problem 3.3. Define \(\alpha_i := \phi(s_i)\) for all \(i = 1, \ldots, n\), where the conformal map \(\phi\) is

\[ \phi : \mathbb{C}_+ \rightarrow \mathbb{D} : s \mapsto \frac{s - 1}{s + 1}. \]

**Problem 3.3** is solvable if and only if there exists an integer set \(\{k_1, \ldots, k_n\}\) such that the Pick matrix \(P(\{k_1, \ldots, k_n\})\),

\[ P(\{k_1, \ldots, k_n\}) := \left[ -\log \beta_p - \log \beta_q + j2\pi (k_q - k_p) \right]^n_{p,q=1} \]

is positive semi-definite.

The next result gives a solution of Problem 3.3 by the Nevanlinna–Pick interpolation.

**Theorem 3.5** ([9,10]). Consider Problem 3.3. Fix \(\sigma > 0\). Define \(\alpha_i\) in the same way as in Theorem 3.4 and \(\zeta_i := \psi_\alpha(-\log \beta_i - j2\pi k_i)\) for \(i = 1, \ldots, n\), where \(\{k_1, \ldots, k_n\}\) is an integer set and the conformal map \(\psi_\alpha\) is

\[ \psi_\alpha : \{s \in \mathbb{C}_+ : 0 < \text{Re} s < \sigma\} \rightarrow \mathbb{D} : s \mapsto \frac{e^{-js\pi/\sigma} - 1}{e^{-js\pi/\sigma} + 1}. \]

If there exists an analytic function \(g : \mathbb{D} \rightarrow \mathbb{D}\) such that \(g(\alpha_i) = \zeta_i\) for \(i = 1, \ldots, n\), then

\[ G(s) := \exp\left( -\frac{s}{2} - \frac{ja}{\pi} \log \left( \frac{1 + g(\phi(s))}{1 - g(\phi(s))} \right) \right) \]

is a solution to Problem 3.3.

**Remark 3.6.** 1. In Theorem 3.4, we have an infinite number of \(P(\{k_1, \ldots, k_n\})\). Note, however, that in order that \(P(\{k_1, \ldots, k_n\})\) be positive semi-definite it is necessary that \(K_{pq} := k_p - k_q\) be bounded. It turns out that only finitely many distinct \(P(\{k_1, \ldots, k_n\})\) could possibly be positive semi-definite. In fact, for the positive semi-definiteness of \(P(\{k_1, \ldots, k_n\})\), \(K_{pq}\) must satisfy the following quadratic inequality:

\[ \det \left[ \begin{array}{cc} -\log \beta_p - \log \beta_q + j2\pi k_{pq} & -\log \beta_p - \log \beta_q + j2\pi k_{pq} \\ 1 - \alpha_p \alpha_q & 1 - \alpha_p \alpha_q \end{array} \right] = \alpha_p^2 + bK_{pq} + c \geq 0, \]

where \(a := -4\pi^2, b := 4\pi Re [(\log \beta_p - \log \beta_q)],\) and

\[ c := \log \beta_p + \log \beta_q \left| 1 - \alpha_p \alpha_q \right|^2. \]

Hence \(D := b^2 - 4ac \geq 0\) and \((b + \sqrt{D})/(2a) \leq K_{pq} \leq (b - \sqrt{D})/(2a)\). Thus we can check the solvability of Problem 3.3 in a finite number of steps. See [23,24] for the details.

2. A function \(f\) is said to be real if \(f(\bar{s}) = f(s)\). Simple calculations show that \(G(s)\) in (10) is real if \(g(z) = j \cdot g_0(z)\), where \(g_0(z)\) is real.

For finite dimensional systems [12–14] and systems with infinitely many unstable modes [9,10], the problem of sensitivity reduction by a stable controller is equivalent to Problem 3.3. On the other hand, the difficulty of strong and robust stabilization is the \(\mathcal{H}^\infty\)-norm condition (4) in Theorem 3.2.

We now develop both a sufficient and a necessary condition for (4). It follows from these conditions that we obtain lower and upper bounds on the perturbation by Problem 3.3. Theorem 3.4 and Remark 3.1 show that we can compute these bounds by calculations of the finitely many Pick matrices. Additionally, we find stable controllers for robust stabilization by Theorem 3.5.

Define \(\rho_{\text{nst}} := \inf_{\omega \in \mathbb{R} \cap (\pi, 2\pi)} \|WT\|_{\infty}\). Then \(K_{\text{nst}} := 1/\rho_{\text{nst}}\) can be regarded as the largest allowable multiplicative uncertainty bound for robust stability with a stable controller. Theorem 3.7 below gives a lower bound of \(K_{\text{nst}}\) and stable robust controllers.

**Theorem 3.7.** Consider Problem 2.3 under Assumptions 2.1 and 2.2. Suppose \(\|W\|_{\infty} < \rho\). Choose \(W_1\), satisfying \(W_1\), \(1/W_1 \in \mathbb{R} \mathcal{H}^\infty\) and \(\|W(j\omega)\|_1 \leq \rho - |W(j\omega)|\) for almost all \(\omega \in \mathbb{R}\). Define \(\beta_i := (M_i(z_i))/(M_d(z_i)\tilde{W}_i(z_i))\) for \(i = 1, \ldots, n\). If \(G\) is a solution of Problem 3.3 with the interpolation data \((z_i; \beta_i)_{i=1}^n\), then \(K_{\text{nst}} \geq 1/\rho\) and

\[ C := W - M_d W_i C \]

\[ W_i M_i W_i C \]

is a solution to Problem 2.3.

**Proof.** Note that \(\beta_i \neq 0\) for each \(i\) because the unit \(W\) does not have unstable zeros. By Theorem 3.2, it suffices to show that there exists \(F\) satisfying (3)–(5).

Let us first obtain a sufficient condition for (4). Since \(M_d\) is inner, \(\|W(j\omega) - M_d(j\omega)F(j\omega)\|_1 \leq \|M_d(j\omega)\|_1 \cdot |F(j\omega)| + \|W(j\omega)\|_1 \leq |F(j\omega)| + \rho - |W(j\omega)|\) for almost all \(\omega \in \mathbb{R}\). Moreover \(\|F(j\omega) + \rho - |W(j\omega)|\|_1 \leq 1\). It follows that if \(\|F/W_i\|_{\infty} \leq 1\), then we have (4).

Suppose \(G\) is a solution of Problem 3.3 with \((z_i; \beta_i)_{i=1}^n\). Define \(F := W_i G\). By the argument given above, \(F\) achieves (4) because \(\|F/W_i\|_{\infty} \leq \|G\|_{\infty} \leq 1\). Since \(G\) and \(W_i\) are unit elements, \(F\) satisfies (3). Moreover the interpolation conditions (5) can be obtained directly by those of \(G\). Thus \(F\) satisfies (3)–(5). By substituting \(F = W_i G\) into (6), we can also derive (11). \(\square\)
In the same way, an upper bound of $K_{\text{sup}}$ can be obtained by the next result:

**Theorem 3.8.** Consider Problem 2.3 under Assumptions 2.1 and 2.2. Choose $W_n$ satisfying $W_n, 1/W_n \in \mathcal{RH}^\infty$ and $|W_n(j\omega)| \geq \rho + |W(j\omega)|$ for almost all $\omega \in \mathbb{R}$. Define $\gamma_i := W(z_i)/(M_{d}(z_i)W_n(z_i))$ for $i = 1, \ldots, n$. If Problem 3.3 with the interpolation data $(\gamma_i)_{i=1}^n$ is not solvable, then $K_{\text{sup}} \leq 1/\rho$.

**Proof.** As in the proof of Theorem 3.7, we can derive a necessary condition for (4) by $|W(j\omega) - M_d(j\omega) F(j\omega)| \geq |F(j\omega)| + \rho - |W_n(j\omega)|$ for almost all $\omega \in \mathbb{R}$. The rest of the proof follows the same lines as that of Theorem 3.7, so it is omitted. \hfill $\square$

**Remark 3.9.** 1. In Assumption 2.1, we have taken a biproper plant having infinitely many unstable poles as the nominal model. Therefore the condition $\|W\|_{\infty} < \rho$ in Theorem 3.7 implies that the controllers obtained by our proposed method may not robustly stabilize strictly proper plants. In the first place, however, we should pose the question: Are strictly proper plants with infinitely many unstable poles stabilizable? The answer is negative; see Appendix.

2. By the MATLAB command `fitmagfrd`, we can compute $W_n, W_n$ in Theorems 3.7 and 3.8.

**Theorem 3.7 generally gives an infinite dimensional controller.** A natural question at this stage is the following: *Does a finite dimensional controller that approximates the derived controller stabilize the plant and satisfy the $\mathcal{H}^\infty$-norm condition (2)?* Rational approximations can be obtained from the frequency response data with approximation methods for stable infinite dimensional systems; see, e.g., [25] and its references.

To ensure that the approximation $C_a \in \mathcal{RH}^\infty$ still stabilizes the plant, we can obtain an error bound on the difference $\|C - C_a\|_{\infty}$.

Define

$$T_a := \frac{PC_a}{1 + PC_a}. \tag{12}$$

The following result illustrates that we can also obtain an upper bound of $\|WT_a\|_{\infty}$ by $\|C - C_a\|_{\infty}$.

**Proposition 3.10.** Let $P \in \mathcal{F}^\infty$ and $W \in \mathcal{RH}^\infty$. Suppose there exists $C \in \mathcal{RH}^\infty \cap \mathcal{R}(P)$ and $C_a \in \mathcal{RH}^\infty \cap \mathcal{R}(P)$. Define $\delta := \|P/(1 + PC)\|_{\infty}$ and $\epsilon := \|C - C_a\|_{\infty}$. If $\delta \epsilon < 1$, then

$$\|WT_a\|_{\infty} \leq \frac{\delta \epsilon \cdot \|W\|_{\infty} + \|WT\|_{\infty}}{1 - \delta \epsilon}, \tag{13}$$

where $T$ and $T_a$ are defined by (2) and (12) respectively.

**Proof.** Routine calculations show that

$$T - T_a = \frac{P}{1 + PC}(1 - T_a)(C - C_a).$$

Hence

$$\|WT - WT_a\|_{\infty} \leq \delta \epsilon \cdot \|W(1 - T_a)\|_{\infty} \leq \delta \epsilon \cdot (\|W\|_{\infty} + \|WT_a\|_{\infty}). \tag{14}$$

Since $\|W\|_{\infty} - \|WT\|_{\infty} \leq \|WT - WT_a\|_{\infty}$, it follows from (14) that

$$(1 - \delta \epsilon) \cdot \|WT_a\|_{\infty} \leq \delta \epsilon \cdot \|W\|_{\infty} + \|WT\|_{\infty}.$$ 

Thus we obtain (13) if $\delta \epsilon < 1$. \hfill $\square$

### 4. Numerical examples

In this section, we present a numerical example to show the effectiveness of the results. We also apply the proposed method to a repetitive control system [15,16]. Repetitive control attempts to track or reject arbitrary periodic signals of a fixed period. Tracking or disturbance rejection of periodic signals appears in many applications, e.g., disk drives [26] and industrial manipulators [27].

**Example 1.** Consider Problem 2.3 with the following infinite dimensional system $P$, weighting function $W$, and positive constant $\rho$:

$$P(s) = \frac{(s - \alpha)(s - 4e^{-s} + 1)}{(s - 10)(s - 15)(2e^{-s} + 1)}.$$

$$W(s) = K \cdot \frac{s + 1}{s + 10}, \quad \rho = 1,$$

where $2 \leq \alpha < 10$ and $K > 0$. Let $p$ be the only root of $s - 4e^{-s} + 1 = 0$ in $\mathbb{C}_+$ (note that $p \approx 0.7990$). Using the factorization method of [20], $P$ can be factorized as $P = M_d N_d / M_d$, where

$$M_d(s) := \frac{(s - \alpha)(s - p)}{(s + \alpha)(s + p)},$$

$$M_d(s) := \frac{(s - 10)(s - 15)(2e^{-s} + 1)}{(s + 10)(s + 15)(e^{-s} + 2)},$$

$$N_d(s) := \frac{(s + \alpha)(s + p)(s - 4e^{-s} + 1)}{(s - p)(s + 10)(s + 15)(e^{-s} + 2)}.$$

Let $K_{\text{sup}}$ be the supremum of $K$ such that there exists $C \in \mathcal{RH}^\infty \cap \mathcal{R}(P)$ satisfying (2). Fig. 2 shows the relationship between $\alpha$ and $K_{\text{sup}}$. In Fig. 2, the solid line shows the lower bound of $K_{\text{sup}}$ obtained by Theorem 3.7, and the dashed line indicates the upper bound of $K_{\text{sup}}$ derived by Theorem 3.8. We compute both $W_n$ and $W_n$ in Theorems 3.7 and 3.8 by the MATLAB function `fitmagfrd`. Both lines in Fig. 2 decrease to 0 as $\alpha$ becomes closer to 10. The reason for this drop is that an unstable pole–zero cancellation occurs in $P$ when $\alpha = 10$.

Let $\alpha = 2$. Then we obtain the lower bound 0.471 and the upper bound 0.771. We also find a stable controller to achieve robust stability for $K = 0.468$ by Theorem 3.5 with $\sigma = 100$. See Fig. 3 of [9] for a discussion on the selection of $\sigma$ based on a specific numerical example.

When $K = 0.468$, $W_1$ in Theorem 3.7 and $g$ in Theorem 3.5 are given by

$$W_1(s) \approx \frac{0.53(s + 10.20)}{(s + 5.86)},$$

$$g(z) = j \cdot g_0(z), \quad \text{where } g_0(z) \approx \frac{1.049z + 1}{z + 1.050}.$$

The above $W_1$ is obtained by `fitmagfrd`. The stable controller that provides robust stability is obtained by (11), where $G(s)$ is defined in (10) with $g(z)$.

Note that $G(s)$ in (10) is real by Remark 3.6.2. A further investigation of $G$ is conducted through an example in [9].
Forexponentialstability,itisnecessaryandsufficientthat
\[ S \subset \mathbb{C} \text{denotethesetoffunctionsthatareboundedandanalyticin} \quad P \text{where}\]
\[ e^{-\varepsilon t} P \]
\[ \text{addition,if} \quad P \subset P \quad e^{-\varepsilon t} \text{is the internal model of any periodic signals with period} \ L. \]
The existence of such an internal model is equivalent to the exponential decay of the error \( e(t) \) under the hypothesis of the exponential stability of the closed-loop system [16]. On the other hand, \( C \) is designed for the desired performance. Our goal in this example is to determine whether there exists \( C \in \mathcal{H}_\infty \) such that \( C = C_0 C \) stabilizes all \( P_\varepsilon \in \mathcal{P} \) and the error \( e(t) \) tends exponentially to zero for any \( P_\varepsilon \in \mathcal{P} \).

For \( \varepsilon > 0 \), let \( C_{\varepsilon} \) denote \( \{s \in \mathbb{C} \mid \text{Re} \ s > -\varepsilon \} \) and let \( \mathcal{H}_\infty \left( C_{\varepsilon} \right) \) denote the set of functions that are bounded and analytic in \( C_{\varepsilon} \). For exponential stability, it is necessary and sufficient that \( S, C, \) and \( P \) belong to \( \mathcal{H}_\infty \left( C_{\varepsilon} \right) \) for some \( \varepsilon > 0 \) [29, Theorem 3.1]. In addition, if \( e \) is sufficiently small, then
\[ \mathcal{P} = \left\{ P_\Delta = (1 + W \Delta)P_0 : \Delta \in \mathcal{H}_\infty \left( C_{\varepsilon} \right), \sup_{\sigma \in C_{\varepsilon}} |\Delta(\sigma)| < 1 \right\} \quad (15) \]
where
\[ P_0 = \frac{(s - 6)(s - 9)}{(s - 5)(s + 8)}, \quad W(s) = \frac{0.25038(s + 0.02384)}{s + 10}. \]

Now let us consider the closed-loop system in Fig. 4. By the preceding discussion, to determine whether there exists \( C \in \mathcal{H}_\infty \) yielding the exponential stability of the closed-loop system for every \( P_\varepsilon \in \mathcal{P} \), we study Problem 2.3 with
\[ \hat{P}(s) := P(s - \varepsilon) = C_0(s - \varepsilon)P_1(s - \varepsilon), \quad (16) \]
\[ \hat{W}(s) := W(s - \varepsilon), \quad \rho := 1. \]

Once we find a solution \( \hat{C} \) of this problem, \( C_0(\cdot) := \hat{C}(\cdot + \varepsilon) \in \mathcal{H}_\infty \left( C_{\varepsilon} \right) \) makes the closed-loop system exponentially stable for every \( \Delta \in \mathcal{H}_\infty \left( C_{\varepsilon} \right) \) satisfying \( \sup_{\sigma \in C_{\varepsilon}} |\Delta(\sigma)| < 1 \) in Fig. 4.

Let \( \varepsilon = 0.001 \), which satisfies (15). \( \hat{P} \) in (16) can be factorized as \( \hat{P} = M_1N_1/M_2, \) where
\[ M_1(s) := \frac{(s - \varepsilon - 6)(s - \varepsilon - 9)}{(s + \varepsilon + 6)(s + \varepsilon + 9)}, \]
\[ M_2(s) := \frac{(e^{-\varepsilon}(s - \varepsilon - 5) - (e^{-\varepsilon} - e^{-\varepsilon}))(s + \varepsilon + 5)}{(s + \varepsilon + 6)(s + \varepsilon + 9)} \]
\[ N_1(s) := \frac{(s + \varepsilon + 6)(s + \varepsilon + 9)}{(e^{-\varepsilon} - e^{-\varepsilon}))(s + \varepsilon + 5)(s - \varepsilon + 8)}. \]

Define \( \hat{T} := \hat{P}C / (1 + \hat{P}C). \) It follows from Theorems 3.7 and 3.8 that 0.71 < inf \( C \in \mathcal{H}_\infty \left( C_{\varepsilon} \right) \|\hat{W}\| \|\hat{T}\| < 0.97. \) The MATLAB function fitmagfrd is used for \( W_1 \) and \( W_2 \) in Theorems 3.7 and 3.8.

Thus there exists \( C \in \mathcal{H}_\infty \) such that the repetitive controller \( C = C_0C \) stabilizes all \( P_\varepsilon \in \mathcal{P} \) and achieves the exponential decay of \( e(t) \) for any \( P_\varepsilon \in \mathcal{P}. \)

5. Concluding remarks

We have studied the strong and robust stabilization problem for single-input single-output infinite dimensional systems. The plants we consider can have only finitely many simple unstable zeros but may possess infinitely many unstable poles. It still remains an open problem to obtain a necessary and sufficient condition for this robust stabilization problem. However, using the modified Nevanlinna–Pick interpolation, we have obtained both lower and upper bounds on the multiplicative perturbation under which a stable controller can stabilize the plant. Moreover we have found stable controllers to achieve robust stability. We have also presented a numerical example to illustrate the results. A repetitive control system has been discussed as an application of the proposed method.

Appendix. Stabilizability of strictly proper plants having infinitely many unstable poles

We answer the question: Can a linear time-invariant controller stabilize a strictly proper plant with an infinite number of unstable poles?

The previous works [30,31] on \( \mathcal{H}_\infty \) control of plants with infinitely many unstable modes assume that the plants are biproper. In addition, a strictly proper neutral delay system is not stabilizable by a finite dimensional controller [32]. However the above question is not fully answered. Based on the Bezout identity, the next result shows that more general strictly proper plants with infinitely many unstable poles are not stabilizable in the sense of [17].

**Proposition A.1.** Let nonzero \( N, D \in \mathcal{H}_\infty \) be weakly coprime in the sense of [17], i.e., every greatest common divisor of \( N \) and \( D \) is a unit element. Suppose \( D \) has infinitely many zeros in \( C_-, \) and that the set of these unstable zeros has no limit points on the imaginary axis. If \( N \) satisfies
\[ \lim_{R \to \infty} \sup_{|s| > R} |N(s)| = 0, \quad (A.1) \]
then \( P := N/D \) is not stabilizable.

**Proof.** Suppose \( P \) is stabilizable. Then by Theorem 1 of [17], there exist \( X, Y \in \mathcal{H}_\infty \) such that
\[ N(s)X(s) + D(s)Y(s) = 1 \quad \text{for all} \ s \in C_+. \quad (A.2) \]
By (A.1), for every \( \varepsilon > 0 \), there exists \( R > 0 \) such that \( |N(s)| \cdot |X(s)| \|Y(s)\| < \varepsilon \) for all \( s \in C_+ \) satisfying \( |s| > R. \) In addition, there exists \( z_0 \in C_- \) such that \( D(z_0) = 0 \) and \( |z_0| > R. \) Otherwise the set of the unstable zeros of \( D \) has at least one limit point in \( \{s \in C_- : |s| \leq R\}, \) which implies that \( D(s) = 0 \) for all \( s \in C_- \). Let \( \varepsilon < 1. \) Then
\[ |N(z_0)X(z_0) + D(z_0)Y(z_0)| \leq |N(z_0)| \cdot |X(s)| < \varepsilon < 1. \]
This contradicts (A.2). Thus \( P \) is not stabilizable. □
