Abstract

Transformation properties of discrete Painlevé equations are investigated by using an algorithmic method. This method yields explicit transformations which relates the solutions of discrete Painlevé equations, discrete P_{II} – P_V , with different values of parameters. The particular solutions which are expressible in terms of the discrete analogue of the classical special functions of discrete Painlevé equations can also be obtained from these transformations.

1. Introduction

Painlevé and his school classified the integrable second order equation of the form $y'' = f(x, y, y')$ where f is rational in y and y' and analytic in x , whose solutions have no movable critical points, and discovered six transcendental equations that are called Painlevé equations, P_I – P_{VI} [1–3]. Their general solutions cannot be expressed in terms of the known elementary functions and can be regarded as nonlinear analogues of the classical special functions. However, P_{II} – P_{VI} have rational solutions and solutions expressible in terms of the classical special functions for certain values of parameters. P_{II} – P_{VI} also possess Bäcklund transformations which relate solutions of the same equation with different values of parameters, or to solution of another equation of Painlevé type [4–6]. Although, Painlevé equations were first discovered from strictly mathematical considerations, they have appeared in physical applications. For example, P_{III} arises in the Ising model [7], and P_{IV} appears in quantum gravity [8].

Discrete analogues of the Painlevé equations are nonautonomous mappings that are integrable in the same sense as the continuous Painlevé equations [9–11], and recently have attracted much attention. The discrete Painlevé equations, d - P_I – d - P_{VI} , which have the form

$$x_{n+1} = \frac{f_1(x_n; n) + x_{n-1}f_2(x_n; n)}{f_3(x_n; n) + x_{n-1}f_4(x_n; n)}, \quad (1.1)$$

where $f_j(x_n; n)$ are polynomials of degree at most four in x_n [12]. In continuous limit, the discrete Painlevé equations yield a Painlevé equation, though some of the discrete Painlevé equations have limits more than one Painlevé equation.

Moreover, discrete Painlevé equations possess properties similar to the ones of the continuous Painlevé equations. For example, discrete Painlevé equations also form coalescence cascades [9,13–15], possess Lax’s pairs [16–18], have rational solutions for certain values of parameters [19–21], have particular solutions for certain parameter values expressible in terms of the discrete analogue of the special functions [16,19,22–24], and have Bäcklund transformations [19,22,24]. Discrete Painlevé equations also appear in physics, for example, the computation of a certain partition function in a model of two-dimensional quantum gravity led discrete P_I [25]. The only difference between continuous and discrete Painlevé equations is that the continuous Painlevé equations have unique canonical form up to a Möbius transformation, but there is more than one inequivalent discrete equation which has the Painlevé equation as its continuous limit.

Recently, Sakai [26] characterized the Painlevé equations in the frame work of the theory of rational surfaces, and showed that the translation part of the affine Weyl groups give rise to discrete Painlevé equations whereas the whole group acts as their groups of symmetries, Bäcklund transformations. The six continues Painlevé equations appear as degenerate cases of this construction. The geometrical description in the framework of the affine Weyl group $E_6^{(1)}$ of the asymmetric q - P_V and asymmetric d - P_{IV} which are known as discrete analogues of the Painlevé VI equation was given in the recent work of Grammaticos et al. [27].

In this article, we investigate the transformation properties of the discrete Painlevé equations by using an algorithmic method which is similar to the method developed by Fokas and Ablowitz [5] for investigating the transformation properties of the continuous equations of the Painlevé type. In [5], for given continuous Painlevé equations

$$v'' = P_2(v')^2 + P_1v' + P_3, \tag{1.2}$$

where P_1, P_2, P_3 depend on v , independent variable z and set of parameters α , the transformation of type

$$u(z; \hat{\alpha}) = \frac{v' + av^2 + bv + c}{dv^2 + ev + f}, \tag{1.3}$$

where a, b, \dots, d depend on z only and $u(z; \hat{\alpha})$ solves some second order equation of the Painlevé type with set of parameters $\hat{\alpha}$ was considered. If we solve (1.3) for v' , we obtain

$$v' = (du - a)v^2 + (eu - b)v + (fu - c). \tag{1.4}$$

That is, solution v of the given equation of Painlevé type also satisfies a Riccati equation with the coefficients depending linearly on the solution u of related Painlevé type equation. By following the similar argument, for a given discrete Painlevé Eq. (1.1) with parameter set α , we consider discrete Riccati equation, that is

$$x_{n+1} = \frac{A_n x_n + B_n}{C_n x_n + D_n}, \tag{1.5}$$

where $A_n = A_{1,n}y_n + A_{0,n}$, $B_n = B_{1,n}y_n + B_{0,n}$, $C_n = C_{1,n}y_n + C_{0,n}$, and $D_n = D_{1,n}y_n + D_{0,n}$ such that y_n solves discrete equation of Painlevé type with parameter set $\hat{\alpha}$. The aim is to determine $A_{j,n}, \dots, D_{j,n}, j = 0, 1$ requiring that (1.5) defines a one-to-one invertible map between the solutions x_n of a given discrete Painlevé equation, and solutions y_n of some second order discrete equation of Painlevé type. This method yields explicit transformations between a given discrete Painlevé equation and the same discrete Painlevé equation but with different values of its parameters, and between two different discrete equations of Painlevé type. As an application of the method, we obtain particular solutions of discrete Painlevé equations in terms of discrete analogue of the classical special functions.

The method can be summarized as follows: From Eq. (1.5), one writes

$$x_{n-1} = -\frac{D_{n-1}x_n - B_{n-1}}{C_{n-1}x_n - A_{n-1}}. \tag{1.6}$$

Substituting x_{n+1} and x_{n-1} given in (1.5) and (1.6) respectively into given discrete Painlevé Eq. (1.1) gives an equation which is polynomial for x_n with the coefficients depending on $A_{j,n}, \dots, D_{j,n}, j = 0, 1, y_n$ and y_{n-1} . Now, we choose $A_{j,n}, \dots, D_{j,n}$ such that the polynomial for x_n reduces to a polynomial of degree one or of degree two. That is,

$$E(y_n, y_{n-1}; n)x_n + F(y_n, y_{n-1}; n) = 0, \tag{1.7}$$

or

$$E(y_n, y_{n-1}; n)x_n^2 + F(y_n, y_{n-1}; n)x_n + G(y_n, y_{n-1}; n) = 0. \tag{1.8}$$

If one solves (1.7) or (1.8) for x_n and substitutes into (1.5), (1.5) yields a discrete equation of Painlevé type for y_n . It turns out that, similar to the case of continuous Painlevé equations, discrete P_{II} – P_V admit transformations of both types (1.7) and (1.8). However, discrete P_{VI} does not admit a transformation of type (1.7). In this article we will consider the transformation of type (1.7), the type (1.8) will be considered later and published elsewhere.

2. Discrete Painlevé II equation

In this section, we consider d-P_{II} equation:

$$x_{n+1} + x_{n-1} = \frac{z_n x_n + a}{1 - x_n^2}, \tag{2.1}$$

where $z_n = \alpha n + \beta$, and α, β, a are constants. Substituting x_{n+1} and x_{n-1} given in (1.5) and (1.6) respectively into (2.1) gives the following polynomial for x_n ,

$$(z_n x_n + a)(C_n x_n + D_n)(C_{n-1} x_n - A_{n-1}) = (1 - x_n^2)[(A_n x_n + B_n)(C_{n-1} x_n - A_{n-1}) - (C_n x_n + D_n)(D_{n-1} x_n - B_{n-1})]. \tag{2.2}$$

Our goal now is to choose A_n, \dots, D_n in such a way that (2.2) becomes a linear equation for x_n . Eq. (2.2) reduces to a linear equation for x_n ,

$$(B_n + B_{n-1} + z_n - 2)x_n = B_n - B_{n-1} - a, \tag{2.3}$$

with the choice of $A_n = C_n = D_n = 1$. Without loss of generality, we may choose $B_n = y_n - \frac{1}{2}z_n - \frac{1}{4}\alpha + 1$. Hence, Eqs. (1.5) and (2.3) respectively give

$$y_n = (x_n + 1)(x_{n+1} - 1) + \frac{1}{2}z_n + \frac{1}{4}\alpha \tag{2.4}$$

and

$$x_n = \frac{y_n - y_{n-1} + v}{y_n + y_{n-1}}, \tag{2.5}$$

where $v = -\frac{1}{2}\alpha - a$. Eliminating x_n between (2.4) and (2.5) leads to a discrete form of P_{XXXIV} [22]:

$$(y_n + y_{n-1})(y_n + y_{n+1}) = \frac{v^2 - 4y_n^2}{y_n - \frac{1}{2}z_n - \frac{1}{4}\alpha}. \tag{2.6}$$

Miura transformation (2.5) was also given in [22].

2.1. Bäcklund transformation for d-P_{II}

Since, (2.6) is quadratic in v , thus $y_n(v) = y_n(-v)$. But then, from Eq. (2.5)

$$\bar{x}_n(-v) = \frac{y_n(-v) - y_{n-1}(-v) - v}{y_n(-v) + y_{n-1}(-v)} = \frac{y_n(v) - y_{n-1}(v) - v}{y_n(v) + y_{n-1}(v)} = x_n(v) - \frac{2v}{y_n(v) + y_{n-1}(v)}. \tag{2.7}$$

Hence, expressing y_n in terms of x_n and using $v = -\frac{1}{2}\alpha - a$ give the following Bäcklund transformation for d-P_{II}

$$\bar{x}_n = x_n - \frac{2v(x_n + 1)}{2(x_{n+1} - 1)(x_n + 1) - z_n x_n - a}; \quad \bar{a} = -a - \alpha. \tag{2.8}$$

Bäcklund transformation for d-P_{II} was also given in [22,24,28].

2.2. Special solution

The transformation (2.5) breaks down if

$$y_n + y_{n-1} = 0 \tag{2.9}$$

and

$$y_n - y_{n-1} + v = 0. \tag{2.10}$$

By solving (2.9) and (2.10), we find that $y_n = v = 0$. Substituting $y_n = v = 0$ into (2.4) yields the following discrete Riccati equation:

$$x_{n+1} = \frac{2x_n - z_n + a + 2}{2(x_n + 1)}. \tag{2.11}$$

Therefore, particular solution of d-P_{II} is characterized by (2.11), iff $a = -\frac{1}{2}\alpha$. Eq. (2.11) can be linearized by a Cole–Hopf transformation $x_n = \frac{w_n}{w_{n-1}} - 1$, and we thus obtain the discrete analogue of the Airy equation:

$$2w_{n+1} + (z_n - a)w_{n-1} - 4w_n = 0. \tag{2.12}$$

Special solution in terms of discrete Airy functions of d-P_{II} was also given in [22–24].

3. Discrete Painlevé III equation

In this section, we consider the following discrete Painlevé III equation, q-P_{III} [14]:

$$x_{n+1}x_{n-1} = \frac{ab(x_n - c\lambda^n)(x_n - d\lambda^n)}{(x_n - a)(x_n - b)}, \tag{3.1}$$

where a, b, c, d are constants. Using the method introduced in Section 1, we find

$$\frac{(A_n x_n + B_n)(D_{n-1} x_n - B_{n-1})}{(C_n x_n + D_n)(C_{n-1} x_n - A_{n-1})} = -\frac{ab(x_n - c\lambda^n)(x_n - d\lambda^n)}{(x_n - a)(x_n - b)}. \tag{3.2}$$

With the choice of $D_n = -aC_n$ and $A_n = bC_n$, Eq. (3.2) can be reduced to the following linear equation for x_n :

$$[bC_n B_{n-1} + aC_{n-1} B_n + ab(c + d)\lambda^{2n} C_n C_{n-1}]x_n = abcd\lambda^{2n} C_n C_{n-1} - B_n B_{n-1}. \tag{3.3}$$

Without loss of generality we may let, $B_n = \mu\lambda^{n+\frac{1}{2}}y_n$, $C_n = 1$, where $\mu^2 = abcd$. Then Eqs. (1.5) and (3.3) become

$$y_n = \frac{x_{n+1}(x_n - a) - bx_n}{\mu\lambda^{n+\frac{1}{2}}} \tag{3.4}$$

and

$$x_n = \frac{\mu^2 \lambda^{n+\frac{1}{2}}(1 - y_n y_{n-1})}{a\mu\lambda y_n + b\mu y_{n-1} + ab\lambda^{\frac{1}{2}}(c + d)}, \tag{3.5}$$

respectively. Eliminating x_n between the Eqs. (3.4) and (3.5) leads to the following discrete equation for y_n

$$(y_n y_{n+1} - 1)(y_n y_{n-1} - 1) = -\frac{\bar{\lambda}^n (y_n - \alpha)(y_n - \frac{1}{\alpha})(y_n - \beta)(y_n - \frac{1}{\beta})}{(\gamma y_n - \bar{\lambda}^n)}, \tag{3.6}$$

where

$$\alpha = -\frac{\mu}{ac\lambda^{\frac{1}{2}}}, \quad \beta = -\frac{\mu}{ad\lambda^{\frac{1}{2}}}, \quad \gamma = -\frac{\mu\lambda^{\frac{1}{2}}}{ab}, \quad \bar{\lambda} = \lambda^{-1}. \tag{3.7}$$

Eq. (3.6) is the special case, $\delta = 0$, of q-P_V [14]:

$$(y_n y_{n+1} - 1)(y_n y_{n-1} - 1) = \frac{\bar{\lambda}^{2n} (y_n - \alpha)(y_n - \frac{1}{\alpha})(y_n - \beta)(y_n - \frac{1}{\beta})}{(\gamma y_n - \bar{\lambda}^n)(\delta y_n - \bar{\lambda}^n)}. \tag{3.8}$$

Thus there exists the one to one correspondence given by (3.4) and (3.5) between the solutions of q-P_{III} and (3.6).

3.1. Bäcklund transformation for discrete P_{III}

Bäcklund transformation can be obtained by finding two sets of $\{\alpha, \beta, \gamma\}$ such that (3.6) is invariant. It should be noted that Eq. (3.6) is invariant under the change of parameters

$$\bar{\alpha} = \frac{1}{\alpha}, \quad \bar{\beta} = \frac{1}{\beta}, \quad \bar{\gamma} = \gamma. \tag{3.9}$$

By using (3.9) and following the same procedure given in Section 2.1, we obtain the following Bäcklund transformation for q-P_{III}

$$\bar{x}_n = \frac{\bar{d}\lambda x_n [ax_{n+1}(x_n - a) + bx_{n-1}(x_n - b) - 2abx_n + ab(c + d)\lambda^n]}{c[bx_{n+1}(x_n - a) + a\lambda^2 x_{n-1}(x_n - b) - (a^2\lambda^2 + b^2)x_n + ab(c + d)\lambda^{n+1}]}; \tag{3.10}$$

$$\bar{a} = \frac{b\bar{d}}{\lambda c}, \quad \bar{b} = \frac{a\lambda\bar{d}}{c}, \quad \bar{c} = \frac{d\bar{d}}{c}.$$

3.2. Special solution

The transformation (3.5) breaks down if

$$y_n y_{n-1} - 1 = 0 \tag{3.11}$$

and

$$a\mu\lambda y_n + b\mu y_{n-1} + ab\lambda^{\frac{1}{2}}(c + d) = 0. \tag{3.12}$$

By solving Eqs. (3.11) and (3.12), we find that $y_n = -\frac{bc}{\mu\sqrt{\lambda}}$, and $\lambda\mu^2 = b^2c^2$. Then, (3.4) leads to the following discrete Riccati equation

$$x_{n+1} = \frac{b(x_n - c\lambda^n)}{x_n - a}. \tag{3.13}$$

Therefore, particular solution of q -P_{III} is characterized by (3.13), iff $\lambda ad = bc$. Eq. (2.11) can be linearized by a Cole–Hopf transformation $x_n = a + \frac{w_n}{w_{n-1}}$, and we thus obtain the discrete analogue of the Bessel equation [16]:

$$w_{n+1} - b(a - c\lambda^n)w_{n-1} + (a - b)w_n = 0. \tag{3.14}$$

The linearizability condition for q -P_{III} and the particular solution expressible in terms of the discrete analogue of the Bessel functions were also obtained in [15,16,29].

4. Discrete Painlevé IV equation

In this section, we consider the discrete Painlevé IV equation, d -P_{IV}:

$$(x_{n+1} + x_n)(x_{n-1} + x_n) = \frac{(x_n^2 - a^2)(x_n^2 - b^2)}{(x_n - z_n)^2 - c^2}, \tag{4.1}$$

where $z_n = \alpha n + \beta$, and a, b, α, β are constants. Eq. (4.1) gives the following equation after substituting x_{n+1} and x_{n-1} respectively given in (1.5) and (1.6),

$$\frac{[C_n x_n^2 + (D_n + A_n)x_n + B_n][C_{n-1} x_n^2 - (D_{n-1} + A_{n-1})x_n + B_{n-1}]}{(C_n x_n + D_n)(C_{n-1} x_n - A_{n-1})} = \frac{(x_n^2 - a^2)(x_n^2 - b^2)}{(x_n - z_n)^2 - c^2}. \tag{4.2}$$

Eq. (4.2) can be reduced to a linear equation for x_n

$$x_n = \frac{-(y_{n-1} - z_n + \mu + \alpha)(y_n - z_n - \mu - \alpha) + z_n^2 - c^2}{y_n + y_{n-1}}, \tag{4.3}$$

with the choice of $A_n = -(y_n - z_n + \mu)$, $B_n = ab$, $C_n = 1$, and $D_n = y_n - z_n - \mu - \alpha$, where $\mu = -\frac{1}{2}(a + b + \alpha)$. With these choices, Eq. (1.5) yields

$$x_{n+1} = \frac{-(y_n - z_n + \mu)x_n + ab}{x_n + y_n - z_n - \mu - \alpha}. \tag{4.4}$$

By eliminating x_n between (4.3) and (4.4), we obtain d -P_{IV}

$$(y_{n+1} + y_n)(y_{n-1} + y_n) = \frac{(y_n^2 - \bar{a}^2)(y_n^2 - \bar{b}^2)}{(y_n - \bar{z}_n)^2 - \bar{c}^2}, \tag{4.5}$$

where

$$\bar{z}_n = z_n + \frac{1}{2}\alpha, \quad \bar{a}^2 = \left[c - \frac{1}{2}(a + b - \alpha) \right]^2, \quad \bar{b}^2 = \left[c + \frac{1}{2}(a + b - \alpha) \right]^2, \quad \bar{c}^2 = \frac{1}{4}(a - b)^2. \tag{4.6}$$

If we replace y_n with \bar{x}_n in (4.4), we thus obtain the following Bäcklund transformation for d-P_{IV}

$$\bar{x}_n = - \frac{[x_{n+1}(x_n - z_n - \mu - \alpha) - x_n(z_n - \mu) - ab]}{(x_{n+1} + x_n)}, \tag{4.7}$$

such that \bar{x}_n solves d-P_{IV} with the parameters $\bar{a}, \bar{b}, \bar{c}$ given by (4.6). The Bäcklund transformation (4.7) for discrete Painlevé IV equation was first given in [19].

4.1. Special solution

The transformation (4.3) breaks down if

$$y_n + y_{n-1} = 0 \tag{4.8}$$

and

$$-(y_{n-1} - z + \mu + \alpha)(y_n - z_n - \mu - \alpha) + z^2 - c^2 = 0. \tag{4.9}$$

$y_n = \mu + \alpha + c = 0$ solve Eqs. (4.8) and (4.9). Eq. (4.4) yields the following discrete Riccati equation,

$$x_{n+1} = \frac{(a + b - c + z_n)x_n + ab}{x_n + c - z_n}, \tag{4.10}$$

after substituting $y_n = \mu + \alpha + c = 0$ [15,19,29]. Therefore, particular solution of d-P_{IV} satisfies (4.10), iff $a + b - 2c = \alpha$. Cole–Hopf transformation $x_n = z_n - c + (w_n/w_{n-1})$ transforms the Riccati equation (4.10) into the following linear equation for w_n :

$$w_{n+1} - (z_n - c + a)(z_n - c + b)w_{n-1} - 2cw_n = 0. \tag{4.11}$$

Eq. (4.11) has been shown to be solvable in terms of the discrete analogues of Hermite functions [19].

5. Discrete Painlevé V equation

In this section, we consider the q-P_V equation

$$(x_n x_{n+1} - 1)(x_n x_{n-1} - 1) = \frac{\lambda^{2n}(x_n - a)(x_n - b)(x_n - \frac{1}{a})(x_n - \frac{1}{b})}{(cx_n - \lambda^n)(dx_n - \lambda^n)}, \tag{5.1}$$

where a, b, c, d are constants. Applying the method introduced in Section 1, we find

$$\frac{[A_n x_n^2 + (B_n - C_n)x_n - D_n][-D_{n-1}x_n^2 + (B_{n-1} - c_{n-1})x_n + A_{n-1}]}{(C_n x_n + D_n)(C_{n-1}x_n - A_{n-1})} = \frac{\lambda^{2n}(x_n - a)(x_n - b)(x_n - \frac{1}{a})(x_n - \frac{1}{b})}{(cx_n - \lambda^n)(dx_n - \lambda^n)}. \tag{5.2}$$

Eq. (5.2) can be reduced to a linear equation for x_n with the choice of $A_n = \mu\lambda^n, B_n = y_n - (a + b)\mu\lambda^n, C_n = y_n$ and $D_n = -abA_n$, where $\mu^2 = \frac{\lambda}{abcd}$. Then Eqs. (5.2) and (1.5) yield

$$x_n = \frac{\mu\lambda^{n-1}(ab\lambda y_{n-1} + y_n) - (\frac{1}{c} + \frac{1}{d})\lambda^n}{y_n y_{n-1} - 1} \tag{5.3}$$

and

$$x_{n+1} = \frac{\mu\lambda^n(x_n - a - b) + y_n}{y_n x_n - ab\mu\lambda^n}, \tag{5.4}$$

respectively. We obtain the following q-P_V for y_n by eliminating x_n between Eqs. (5.3) and (5.4):

$$(y_n y_{n+1} - 1)(y_n y_{n-1} - 1) = \frac{\lambda^{2n}(y_n - \alpha)(y_n - \frac{1}{\alpha})(y_n - \beta)(y_n - \frac{1}{\beta})}{(\gamma y_n - \lambda^n)(\delta y_n - \lambda^n)}, \tag{5.5}$$

where $\gamma = \frac{1}{a\mu}$, $\delta = \frac{1}{b\mu}$, $\alpha = \frac{\mu c}{\lambda}$, and $\beta = \frac{\mu d}{\lambda}$. Therefore, we have the following Bäcklund transformation for q-P_V

$$\begin{aligned} \bar{x}_n &= \frac{\mu\lambda^n [abx_{n+1} + x_n - a - b]}{x_n x_{n+1} - 1}; \\ \bar{a} &= \frac{\mu c}{\lambda}, \quad \bar{b} = \frac{\mu d}{\lambda}, \quad \bar{c} = \frac{1}{a\mu}, \quad \bar{d} = \frac{1}{b\mu}. \end{aligned} \tag{5.6}$$

5.1. Special solution

The transformation (5.3) breaks down if

$$y_n y_{n-1} - 1 = 0 \tag{5.7}$$

and

$$\mu\lambda^{n-1} (ab\lambda y_{n-1} + y_n) - \left(\frac{1}{c} + \frac{1}{d}\right)\lambda^n = 0. \tag{5.8}$$

If we substitute the solutions $y_n = \frac{\lambda}{\mu c}$, and $\lambda^2 = \mu^2 c^2$ of (5.7) and (5.8) into (5.4), we obtain the following discrete Riccati equation [29],

$$x_{n+1} = \frac{\lambda^n (x_n - a - b) + abd}{ab(dx_n - \lambda^n)}. \tag{5.9}$$

Therefore, particular solution of q-P_V is characterized by (5.9), iff $c = \lambda abd$. Eq. (2.11) can be linearized by a Cole–Hopf transformation $x_n = \frac{\lambda^n}{d} \left(1 - \frac{w_n}{w_{n-1}}\right)$, and we thus obtain the following linear equation for w_n

$$w_{n+1} - \frac{1}{\lambda} \left(\frac{1}{a} - \frac{d}{\lambda^n}\right) \left(\frac{1}{b} - \frac{d}{\lambda^n}\right) w_{n-1} + \left(\frac{1}{ab\lambda} - 1\right) w_n = 0. \tag{5.10}$$

The linearization condition of q-P_V was also given in [30], and shown that x_n can be expressed in terms of discrete analogue of confluent hypergeometric functions.

6. Conclusion

In this article, we have presented an algorithm which is similar to the algorithm introduced in [5] for continuous Painlevé equations, to obtain the Bäcklund transformations for discrete P_{II}–P_V. The algorithm is simple and based on the investigation of discrete Riccati Eq. (1.5) for the solution of a given discrete Painlevé equation, with the coefficients depending linearly on the solution of another discrete equation of Painlevé type. The Miura transformation for d-P_{II} and d-P_{XXXIV}, and the Bäcklund transformation for d-P_{II} and d-P_{IV} that we have presented, were previously known. The special-function solutions for the discrete Painlevé equations are extensively covered in the literature. But the transformations for q-P_{III} and q-P_V were not discussed in the literature before. Moreover, as an application of the algorithm, we have presented the special solutions which are discrete analogue of the classical special functions, for discrete P_{II}–P_V whenever the parameters satisfy certain conditions (the linearizability conditions).
