Abstract: The skew Toeplitz approach is one of the well developed methods to design $H^\infty$ controllers for infinite dimensional systems. In order to be able to use this method the plant needs to be factorized in some special manner. This paper investigates the largest class of SISO time delay systems for which the special factorizations required by the skew Toeplitz approach can be done. Reliable implementation of the optimal controller is also discussed. It is shown that the finite impulse response (FIR) block structure appears in these controllers not only for plants with I/O delays, but also for general time-delay plants.

Keywords: $H^\infty$ control, time-delay, mixed sensitivity problem

1. INTRODUCTION

There are many well-developed techniques for finding $H^\infty$ optimal and suboptimal controllers for systems with time delays. In particular, when the plant is a dead-time system: $e^{-hs}P_0(s)$ where $P_0$ is a rational SISO plant, the optimal $H^\infty$ control problem is solved by (Zhou and Khargonekar, 1987), (Foiaş et al., 1986), using operator theoretic methods; see also (Smith, 1989), (Özbay, 1990) and their references. State-space solution to the same problem is given in (Tadmor, 1997), and (Meinsma and Zwart, 2000). Notably, (Meinsma and Zwart, 2000) used $J$-spectral factorization approach to solve the MIMO version of the problem. Moreover they showed the finite impulse response (FIR) structure appearing in the reliable implementation of the $H^\infty$ controllers for dead-time systems. (Meinsma and Mirkin, 2005) extended this result to the multi-delay dead-time systems (input/output delay case).

A closed-form controller formula is obtained by (Kashiha and Yamamoto, 2003) for the sensitivity minimization problem involving pseudorational plants. For more general infinite dimensional plants a solution is given by (Foiaş et al., 1996). Their approach needs inner-outer factorization of the plant. (Toker and Özbay, 1995) simplified this method and brought into a compact form.

(Kashiha, 2005) obtained an expression for the optimal $H^\infty$ controller for the plants that can be expressed as a cascade connection of a finite-dimensional generalized plant and a scalar inner function. As it was done by (Mirkin, 2003), the solution is reduced to solving two algebraic Riccati equations and an additional one-block...
problem. Moreover, (Kashima, 2005) gave the inner-
outer factorizations of stable pseudorational systems.

In our study, we determine the largest class of time-
delay systems (TDS) for which the Skew-Toeplitz app-

roach of (Foias et al., 1996) is applicable. In order to
use this method it is necessary to do inner-outer
factorizations of the plant. An additional assumption
is that the infinite dimensional plant has finitely many
unstable zeros or poles. In this paper, we give necessary
and sufficient conditions for TDS to have finitely many
unstable zeros or poles. We classify the TDS and give
conditions such that the desired factorization is pos-
sible. For admissible plants, the factorization is given
and optimal \( H^\infty \) controller is obtained. The unstable pole-
zero cancellation in the optimal controller expression
of (Toker and Özbay, 1995) is eliminated. This way
we establish the link between (Toker and Özbay, 1995)
and (Meinsma and Zwart, 2000) by showing the FIR
structure appearing in \( H^\infty \) controllers for not only
dead-time plants, but also for more general TDS.

\section{PRELIMINARY DEFINITIONS AND RESULTS}

In (Foias et al., 1996; Toker and Özbay, 1995), it is
assumed that the plant is in the form
\[
\dot{P}(s) = \frac{\tilde{m}_{i}(s)\tilde{N}_{a}(s)}{\tilde{m}_{a}(s)}
\]
(1)
where \( \tilde{m}_{i}(s) \) is inner, infinite dimensional and \( \tilde{m}_{a}(s) \)
is inner, finite dimensional and \( \tilde{N}_{a}(s) \) is outer, possibly
infinite dimensional. The optimal \( H^\infty \) controller,
\( \mathcal{C}_{\text{opt}} \), stabilizes the feedback system and achieves the
minimum \( H^\infty \) cost,
\[
\gamma_{\text{opt}} = \left\| \left[ \begin{array}{c} \dot{W}_{1}(1 + \mathcal{P}\mathcal{C}_{\text{opt}})^{-1} \\ \dot{W}_{2}\mathcal{P}\mathcal{C}_{\text{opt}}(1 + \mathcal{P}\mathcal{C}_{\text{opt}})^{-1} \end{array} \right] \right\|_{\infty}
\]
(2)
where \( \dot{W}_{1} \) and \( \dot{W}_{2} \) are finite dimensional weights of the
mixed sensitivity minimization problem.

Recently, the optimal \( H^\infty \) control problem is solved by
(Güımüşsoy and Özbay, 2004) for systems with in-
finitely many unstable poles and finitely many unstable
zeros by using the duality with the problem (2). In this
case, the plant has a factorization
\[
\dot{P}(s) = \frac{\tilde{m}_{d}(s)\tilde{N}_{a}(s)}{\tilde{m}_{a}(s)}
\]
(3)
where \( \tilde{m}_{d}(s) \) is inner, infinite dimensional, \( \tilde{m}_{d}(s) \) is finite
dimensional, inner, and \( \tilde{N}_{a}(s) \) is outer, possibly infinite
dimensional. For this dual problem, the optimal con-
troller, \( \mathcal{C}_{\text{opt}} \), and minimum \( H^\infty \) cost,
\( \gamma_{\text{opt}} \), are found for the mixed sensitivity minimization problem
\[
\gamma_{\text{opt}} = \left\| \left[ \begin{array}{c} \dot{W}_{1}(1 + \mathcal{P}\mathcal{C}_{\text{opt}})^{-1} \\ \dot{W}_{2}\mathcal{P}\mathcal{C}_{\text{opt}}(1 + \mathcal{P}\mathcal{C}_{\text{opt}})^{-1} \end{array} \right] \right\|_{\infty}.
\]
(4)
In this paper we consider general delay systems:
\[
P(s) = \frac{r_{p}(s)}{t_{p}(s)} = \frac{\sum_{i=1}^{n}r_{p,i}(s)e^{-h_{i}s}}{\sum_{j=1}^{m}t_{p,j}(s)e^{-\tau_{j}s}}
\]
(5)
satisfying the assumptions
\begin{enumerate}
\item[(A.1)] \( r_{p,i}(s) \) and \( t_{p,j}(s) \) are polynomials with real
coefficients;
\item[(b)] \( h_{1}, \tau_{j} \) are rational numbers such that \( 0 < h_{1} < h_{2} < \ldots < h_{n} \), and \( 0 < \tau_{1} < \tau_{2} < \ldots < \tau_{m} \),
with \( h_{1} \geq \tau_{1} \);
\item[(c)] define the polynomials \( r_{p,i_{\text{max}}}(s) \) and \( t_{p,j_{\text{max}}}(s) \)
with largest polynomial degree in \( r_{p,i}(s) \) and \( t_{p,j}(s) \) respectively (the smallest index if there
is more than one), then, \( \deg\{r_{p,i_{\text{max}}}(s)\} \leq \deg\{t_{p,j_{\text{max}}}(s)\} \) and \( \Delta_{\text{max}} \geq \tau_{\text{max}} \) where \( \deg\{\cdot\} \) denotes the degree of the polynomial;
\item[(A.2)] \( P \) has no imaginary axis zeros or poles;
\item[(A.3)] \( P \) has finitely many unstable poles or zeros, or
equivalently \( r_{p}(s) \) or \( t_{p}(s) \) has finitely many zeros in \( \mathbb{C}_{+} \);
\item[(A.4)] \( P \) can be written in the form of (1) or (3).
\end{enumerate}

Conditions stated in A.1 are not restrictive. In most
cases A.2 can be removed if the weights are chosen
in a special manner. The conditions A.3 – A.4 come
from the Skew-Toeplitz approach. It is not easy to
check assumptions A.3 – A.4, unless a quasi-root
polynomial root finding algorithm is used. We will give a necessary
and sufficient condition to check the assumption A.3 in
section 2.1 and give conditions to check the assumption
A.4 in section 3.1.

By simple rearrangement, \( P \) can be written as,
\[
P(s) = \frac{R(s)}{T(s)} = \frac{\sum_{i=1}^{n}R_{i}(s)e^{-h_{i}s}}{\sum_{j=1}^{m}T_{j}(s)e^{-\tau_{j}s}}
\]
(6)
where \( R_{i} \) and \( T_{j} \) are finite dimensional, stable, proper
transfer functions. The assumptions A.1 – A.4 and
rearrangement of the plant are illustrated on the following
e xample. Consider the system
\[
\begin{align*}
\hat{x}_{1}(t) &= -x_{1}(t - 0.2) - x_{2}(t) + u(t) + 2u(t - 0.4), \\
\hat{x}_{2}(t) &= 5x_{1}(t - 0.5) - 3u(t) + 2u(t - 0.4), \\
y(t) &= x_{1}(t).
\end{align*}
\]
(7)
whose transfer function is in the form
\[
P(s) = \frac{r_{p}(s)}{t_{p}(s)} = \frac{\sum_{i=1}^{2}r_{p,i}(s)e^{-h_{i}s}}{\sum_{j=1}^{3}t_{p,j}(s)e^{-\tau_{j}s}} = \frac{(s + 3)e^{-0.8s} + 2(s - 1)e^{-0.4s}}{s^{2}e^{-0.2s} + 5se^{-0.2s} + 5se^{-0.5s}}
\]
(8)
Note that \( r_{p,i} \) and \( t_{p,j} \) are polynomials with real
coefficients, delays are nonnegative with increasing
order. By \( i_{\text{max}} = 1 \) and \( j_{\text{max}} = 1 \), \( h_{1} = 0 \geq \tau_{1} = 0 \) and \( \deg\{r_{p,1}(s)\} = 1 \leq \deg\{t_{p,1}(s)\} = 2 \).
Therefore, assumption A.1 is satisfied. The plant, \( P \)
has no imaginary axis poles or zeros (assumption
A.2). The denominator of the plant, \( t_{p}(s) \) has finitely many unstable zeros at \( 0.4672 \pm 1.8890j \), whereas
\( r_{p}(s) \) has infinitely many unstable zeros converging to
\( 1.7329 - 5k + 2.5j \) as \( k \to \infty \). Therefore, plant
has finitely many unstable poles satisfying assumption
A.3. One can show that the plant can be factorized as
(1). In this example we have
\[
\text{P} = \frac{R}{T} = \frac{\sum_{i=1}^{2}R_{i}(s)e^{-h_{i}s}}{\sum_{j=1}^{3}T_{j}(s)e^{-\tau_{j}s}}
\]
(9)
where
\[
R_{i}(s) = \frac{r_{p,i}(s)}{(s + 1)^{2}}, \quad \text{and} \quad T_{j}(s) = \frac{t_{p,j}(s)}{(s + 1)^{2}}
\]
are stable proper finite dimensional transfer functions.
Below we give conditions such that A.3 – A.4 can be checked easily.
2.1 Time Delay Systems with Finitely Many Unstable Zeros or Poles

Definition 2.1. Consider \( R(s) = \sum_{i=1}^{n} R_i(s)e^{-h_is} \) where each \( R_i \) is a rational, proper, stable transfer function with real coefficient, and \( 0 \leq h_1 < h_2 < \ldots < h_n \). Let relative degree of \( R_i \) be \( d_i \), then
(i) if \( d_1 < \max\{d_2, \ldots, d_n\} \), then \( R(s) \) is a retarded-type time-delay system (RTDS),
(ii) if \( d_1 = \max\{d_2, \ldots, d_n\} \), then \( R(s) \) is a neutral-type time-delay system (NTDS),
(iii) if \( d_1 > \max\{d_2, \ldots, d_n\} \), then \( R(s) \) is an advanced-type time-delay system (ATDS).

Note that if \( R \) and \( T \) are ATDS, plant has always infinitely many unstable zeros and poles which is not a valid plant for Skew-Toeplitz approach. It is well-known that RTDS has finitely unstable zeros on the right-half plane, (Bellman and Cooke, 1963). Therefore, we will give a necessary and sufficient condition to check whether a NTDS has finitely many or infinitely many unstable zeros with the following lemma:

Lemma 2.1. Assume that \( R(s) \) is a NTDS with no imaginary axis zeros and poles, then the system, \( R \), has finitely many unstable zeros if and only if all the roots of the polynomial, \( \varphi(r) = 1 + \sum_{i=2}^{n} \xi_i r^{h_i-h_1} \) has magnitude greater than 1 where
\[
\xi_i = \lim_{\omega \to \infty} R_i(j\omega)R_1^{-1}(j\omega) \quad \forall \ i = 2, \ldots, n,
\]
\[
h_i = h_1 \sum_{l=1}^{N} \hat{h}_i \in \mathbb{Z}, \quad \forall \ i = 1, \ldots, n.
\]

Proof. Since delays are rational numbers, there exist positive integers \( N \) and \( \hat{h}_i \). If \( R(s) \) is a NTDS, there is no root with real part extending to infinity, i.e.,
\[
\frac{|R(s)|e^{h_1s}}{|R_1(s)|} = 1 - \lim_{\sigma \to \infty} \sum_{i=2}^{n} \xi_i e^{-(h_i-h_1)\sigma} > 0
\]
where \( s = \sigma + j\omega \). Therefore, NTDS may have infinitely many unstable zeros extending to infinity in imaginary part with bounded positive real part, see (Bellman and Cooke, 1963). \( R(s) \) has finitely many unstable zeros if and only if \( R(\sigma + j\omega) \) has finitely many zeros as \( \omega \to \infty \) and \( 0 < \sigma < \sigma_0 < \infty \). Equivalently, \( R(\sigma + j\omega) \) has finitely many unstable zeros if and only if
\[
\lim_{\omega \to \infty} \frac{R(s)}{R_1(s)e^{-h_1s}} = 1 + \sum_{i=2}^{n} \xi_i e^{h_i-h_1} \quad (10)
\]
has finitely many unstable zeros where \( r = e^{-\left(\frac{\sigma+\omega}{N}N\right)} \).

Let \( r_0 \) be the root of (10). Then,
\[
|r_0| = e^{\frac{\sigma}{N}N} \quad \sigma = -N\ln|r_0|.
\]
Therefore, the system \( R \) has finitely many unstable zeros if and only if all the roots of the polynomial (10) has magnitude greater than one. Note that if there exists a root \( r_0 \) of (10) with \( |r_0| \leq 1 \), then there are infinitely many unstable zeros of \( R \) converging to \( r_{0,k} = -\frac{\ln|r_0|}{N} - jN(\omega r_0 + 2\pi k) \) as \( k \to \infty \) where \( k \in \mathbb{Z} \) and \( \omega r_0 \) is the phase of the complex number \( r_0 \).

Corollary 2.1. The time-delay system \( R \) has finitely many unstable zeros if and only if \( R \) is a RTDS or \( R \) is a NTDS satisfying Lemma 2.1.

A time delay system with finitely many unstable zeros will be called an \( F \)-system. We define the conjugate of \( R(s) = \sum_{i=1}^{n} R_i(s)e^{-h_is} \) as \( \bar{R}(s) := e^{-h_is}R(-s)M_C(s) \) where \( M_C \) is inner, finite dimensional whose poles are poles of \( R \). For the above example, we have
\[
R(s) = \frac{s + 3 + 2(s - 1)e^{-0.4s}}{(s + 1)^2}
\]
where \( b_1 = 0, b_2 = 0.4 \) and \( M_C(s) = \left(\frac{s+1}{s+1}\right)^2 \). So, the conjugate of \( R(s) \) can be written as,
\[
R(s) = \frac{2(s+1)+(s-3)e^{-0.4s}}{(s+1)^2}.
\]

Corollary 2.2. The time-delay system \( \bar{R} \) has finitely many unstable zeros if and only if \( R \) is a ATDS or \( R \) is a NTDS with \( \bar{R} \) satisfying Lemma 2.1.

The system \( R \) whose conjugate \( \bar{R} \) has finitely many unstable zeros is an \( I \)-system. Using Corollary 2.1, an equivalent condition for assumption A.3 is the following.

Corollary 2.3. Plant (6) has finitely many unstable zeros or poles if and only if \( R \) or \( T \) is an \( F \)-system.

Using Corollary 2.3, it is easy to check whether the plant has finitely many unstable zeros or poles. After putting the plant in the form (6), if \( R \) or \( T \) is RTDS, then assumption A.3 is satisfied; if \( R \) or \( T \) is NTDS and Lemma 2.1 is satisfied at least for one of them, then assumption A.3 holds.

It is well known that, since \( R \in \mathcal{H}^\infty \), functions in the form \( R \) admit inner outer factorizations
\[
R = m_n N_o
\]
where \( m_n \) is inner and \( N_o \) is outer. To illustrate this first assume that \( R \) is an \( F \)-system. By Corollary 2.1, it has finitely many unstable zeros. Define an inner function \( M_R \) whose zeros are unstable zeros of \( R \). Note that \( M_R \) is finite dimensional, rational function. Then, \( R \) can be factorized as in (12) where \( m_n = M_R \) and \( N_o = \frac{R}{M_R} \). Note that unstable zeros of \( R \) are cancelled by zeros of \( M_R \), therefore \( N_o \) is outer and \( m_n \) is inner by construction of \( M_R \). Similarly, if \( R \) is an \( I \)-system, By Corollary 2.2, \( \bar{R} \) has finitely many unstable zeros. Define an inner function \( M_{\bar{R}} \) whose zeros are unstable zeros of \( \bar{R} \). Using this result, \( R \) can be factorized as in (12) where \( m_n = \frac{R}{M_{\bar{R}}} \) and \( N_o = \frac{R}{M_R} \).

Corollary 2.4. The plant \( P = \frac{R}{T} \) satisfies A.3 \(- A.4 \) if one of the following conditions are valid:

i) \( R \) is \( I \)-system and \( T \) is \( F \)-system (IF plant),
ii) \( R \) is \( F \)-system and \( T \) is \( I \)-system (FI plant),
iii) \( R \) is \( F \)-system and \( T \) is \( F \)-system (FF plant).

Proof. The TDS (6) should have finitely many unstable zeros or poles to apply Skew-Toeplitz approach. By Corollary 2.1, \( R \) or \( T \) should a \( F \)-system which covers all the cases except \( R \) and \( T \) are \( I \)-systems. Recall that \( P \) can be factorized as
\[ P = \frac{R}{T} = \frac{m_n R N_{o,p}}{m_n T N_{o,T}} = \frac{m_n R}{m_n T} N_o \]

where \( N_o = \frac{N_o}{m_n R} \) is outer function. Note that when \( R \) is \( F \) or \( I \)-system, \( m_n R \) is finite or infinite dimensional respectively. Similarly, when \( T \) is \( F \) or \( I \)-system, \( m_n T \) is finite or infinite dimensional respectively. Therefore, the plant (6) can be factorized as (1) or (3).

**Remarks:**

(1) By Corollary 2.4, it is easy to check whether assumptions A.3 – A.4 are satisfied or not. For the plant (9) in the example, \( T \) is a RTDS, by Corollary 2.1, \( T \) is an \( F \)-system. If \( T \) is a NTDS and \( R \) satisfies Corollary 2.2, therefore, \( R \) is a \( I \)-system, i.e., \( \varphi (r) \) for \( R \) (11) is 1 + \( \frac{1}{z^r} \) and root of the polynomial has magnitude greater than 1.

(2) One can show that \( R \) or \( T \) has infinitely many imaginary axis zeros if and only if corresponding \( \varphi (r) \) has a root with magnitude 1 in Lemma 2.1. Since by assumption A.2, \( P \) has no imaginary axis poles or zeros, this possibility is eliminated. If, in fact, \( P \) does not have infinitely many imaginary-axis poles or zeros, the magnitude of roots of \( \varphi (r) \) is never equal to 1.

(3) For a given system \( R \), if magnitudes of all roots of \( \varphi (r) \) in Lemma 2.1 are smaller than one, then \( R \) is an \( I \)-system.

(4) \( R \) is an \( F \)-system if and only if \( R \) is an \( I \)-system.

### 2.2 FIR Part of the Time Delay Systems

We now show a special structure of time delay systems. This key lemma is used in the next section.

**Lemma 2.2.** Let \( R \) be as in Lemma 2.1 and \( M_R \) be a finite dimensional system whose zeros are included in the zeros of \( R \). Let \( S^+_n \) be the set of common \( \mathbb{C}_+ \) zeros of \( R \) and \( M_R \). Then \( \frac{R}{M_R} \) can be decomposed as

\[ \frac{R}{M_R} = H_R(s) + \mathcal{F}_R(s) \]

where \( H_R \) is a system whose poles are outside of \( S^+_n \) and the impulse response of \( \mathcal{F}_R \) has finite support (by a slight abuse of notation we say \( \mathcal{F}_R \) is an FIR filter).

**Proof.** For simplicity assume that \( z_1, z_2, \ldots, z_{n_t} \in S^+_n \) are distinct. We can rewrite \( \frac{R}{M_R} \) as

\[ \frac{R}{M_R} = \sum_{i=1}^{n_t} \frac{B_i}{M_R} e^{-h_i s} \]

and decompose each term by partial fraction,

\[ \frac{B_i}{M_R} = H_i + F_i \]

where the poles of \( F_i \) are elements of \( S^+_n \) and define the terms \( H_R \) and \( \mathcal{F}_R \) as

\[ H_R(s) = \sum_{i=1}^{n_t} H_i(s) e^{-h_i s} \]

\[ \mathcal{F}_R(s) = \sum_{i=1}^{n_t} F_i(s) e^{-h_i s} \]

where \( F_i \) is strictly proper and \( \mathcal{F}_R(z_k) \) is finite \( \forall i = 1, \ldots, n_t \). The lemma ends if we can show that \( \mathcal{F}_R \) is FIR filter. Inverse Laplace transform of \( \mathcal{F}_R \) can be written as

\[ f_R(t) = \sum_{k=1}^{n_t} \left[ \sum_{i=1}^{n_t} \text{Res}\{F_i(s)\}_{s=z_k} e^{z_k t} (u(t-h_i)) u_h(t) \right] \]

where \( u_h(t) = u(t-h_i), u(t) \) and \( \text{Res}(.) \) are unit step function and the residue of the function respectively. For \( t > h_n \), we have

\[ f_R(t) = \sum_{k=1}^{n_t} e^{z_k t} \left[ \sum_{i=1}^{n_t} \text{Res}\{F_i(s)\}_{s=z_k} e^{-h_i z_k} \right]. \]

Since, \( \text{Res}\{F_i(s)\}_{s=z_k} = R_i(z_k) \text{Res}\{M_R(s)\}_{s=z_k} \),

\[ f_R(t) = \sum_{k=1}^{n_t} \left[ e^{z_k t} \text{Res}\{M_R(s)\} \right]_{s=z_k} R_i(z_k) = 0 \]

for \( t > h_n \) using the fact \( \{z_k\}_{k=1}^{n_t} \) are the zeros of \( R \). Therefore, we can conclude that \( \mathcal{F}_R \) is a FIR filter with support \( [0, h_n] \). Note that the above arguments are also valid for common zeros with multiplicities in \( S^+_n \).

Note that this decomposition eliminates unstable pole-zero cancellation in \( \frac{R}{M_R} \) and brings it into a form which is easy for numerical implementation. Lemma 2.2 explains the FIR part of the \( \mathcal{H}_\infty \) controllers as shown below. Assume that \( R \) is defined as in Definition 2.1 and \( R_0 \) is a bi-proper, finite dimensional system. By partial fraction, \( \frac{R}{M_R} = R_{i, r} + R_{i, 0, 0} \forall i = 1, \ldots, n \), where the \( R_{i, 0, 0} \) is strictly proper transfer function whose poles are the same as the zeros of \( R_0 \). Then, the decomposition operator, \( \Phi \), is defined as

\[ \Phi(R, R_0) = H_R + \mathcal{F}_R \]

where \( H_R = \sum_{i=1}^{n} R_{i, r} e^{-h_i s} \) and \( \mathcal{F}_R = \sum_{i=1}^{n} R_{i, 0, 0} e^{-h_i s} \) are infinite dimensional systems. Note that if the zeros of \( R_0 \) are also unstable zeros of \( R \), then \( \mathcal{F}_R \) is a FIR filter by Lemma 2.2.

### 3. MAIN RESULTS

In this section, we construct the optimal \( \mathcal{H}_\infty \) controller for the plant \( P \), (6), satisfying assumptions A.1 – A.4. By Corollary 2.4, the plant, \( P = \frac{R}{M_R} \), is assumed to be either IF, FI or FF plant.

For each case, we will find optimal \( \mathcal{H}_\infty \) controller and obtain a structure where there is no internal unstable pole-zero cancellation in the controller.

#### 3.1 Factorization of the Plants

In order to apply the Skew-Toeplitz approach, we need to factorize the plant as in (1) or (3).

**3.1.1. IF Plant Factorization**

Assume that the plant in (6) satisfies A.1 – A.4, and \( R \) is \( I \)-system and \( T \) is \( F \)-system. Then \( P \) is in the form (1), where

\[ \tilde{m}_n = e^{-(h_i - \tau_i - \tau_0) s} \frac{(e^{\tau_i s} R)}{R}, \quad \bar{m}_d = M_T, \]

\[ \tilde{N}_0 = \frac{\tilde{R}}{M_T \{e^{\tau_i s} T\}}, \quad \bar{N}_0 = \frac{R}{M_T \{e^{\tau_i s} T\}} \]

where \( M_T \) is an inner function whose zeros are the unstable zeros of \( R(s) \). Since \( R \) is \( I \)-system, conjugate of \( R \) has finitely many unstable zeros, so \( M_T \) is well-defined. Similarly, zeros of \( M_T \) are unstable zeros of \( T \). Note that \( \tilde{m}_n \) and \( \bar{m}_d \) are inner functions, infinite and finite dimensionally respectively. \( \bar{N}_0 \) is an outer term.

**3.1.2. FI Plant Factorization**

Let the plant (6) satisfy A.1 – A.4 (with \( h_1 = \tau_1 = 0 \)), and assume \( R \) is \( F \)-system and \( T \) is \( I \)-system. Then the plant \( P \) can be factorized as in (3),

\[ \tilde{m}_n = M_T \frac{T}{M_R \{e^{\tau_i s} T\}}, \quad \bar{m}_d = M_R(s), \quad \tilde{N}_0 = \frac{R}{M_T \{e^{\tau_i s} T\}} \]

The zeros of \( M_R \) are right half plane zeros of \( R \). The unstable zeros of \( T(s) \) are the same as the zeros of \( M_T \). Similar to previous section, conjugate of \( T \) has finitely many unstable zeros since \( T \) is an \( I \)-system.
The right half plane pole-zero cancellations in \( \tilde{m}_n \) and \( \tilde{N}_n \) will be eliminated in Section 3.2.2 by the method of Section 2.2.

### 3.1.3. FF Plant Factorization

Let \( P = R/T \) satisfy \( A_1 - A_4 \), with \( R \) and \( T \) being \( F \)-systems. In this case \( P \) is in the form (1), 
\[
\tilde{m}_n = e^{-(h_1-T_1)}M_R, \quad \tilde{m}_d = M_T(s), \\
\tilde{N}_n = \{e^{h_1+R}/M_T \{e^{*T+T}/M_R \}
\]
(14)
where \( M_R \) and \( M_T \) are inner functions whose zeros are unstable zeros of \( R \) and \( T \) respectively. Note that when \( h_1 = T_1 = 0 \), \( \tilde{m}_n \) is finite dimensional. Then, exact unstable pole-zero cancellations are possible in this case (except the ones in \( \tilde{N}_n \)).

### 3.2 Optimal \( \mathcal{H}^\infty \) Controller Design

Optimal \( \mathcal{H}^\infty \) controllers for problems (2) and (4) are given in (Toker and Özbay, 1995) and (Gümüşsoy and Özbay, 2004) for the plants (1) and (3) respectively. Given the plant and the weighting functions, the optimal \( \mathcal{H}^\infty \) cost, \( \gamma^\text{opt} \) can be found as described in these papers. Then, one needs to compute transfer functions labeled as \( E_{\gamma^\text{opt}}, F_{\gamma^\text{opt}} \) and \( L \). Due to space limitations we skip this procedure, see (Toker and Özbay, 1995) and (Gümüşsoy and Özbay, 2004) for full details. Instead, we now simplify the structure of the controllers so that a reliable implementation is possible, i.e. there are no internal unstable pole-zero cancellations.

#### 3.2.1. Controller Structure of IF Plants

By using the method in (Toker and Özbay, 1995; Foias et al., 1996), the optimal controller can be written as,
\[
\hat{C}_{\gamma^\text{opt}} = \frac{K_{\gamma^\text{opt}} \{e^{*T+T}/M_T \}}{R + e^{*T}RF_{\gamma^\text{opt}}L} 
\]
(15)
where \( K_{\gamma^\text{opt}} = E_{\gamma^\text{opt}}F_{\gamma^\text{opt}}M_TL \). In order to obtain this structure of controller:

1. Do the necessary cancellations in \( K_{\gamma^\text{opt}} \).
2. Partition, \( K_{\gamma^\text{opt}} \) as, \( K_{\gamma^\text{opt}} = \theta_{\gamma^\text{opt}}\theta_T \) where \( \theta_{\gamma^\text{opt}} \) is a bi-proper transfer function. The zeros of \( \theta_{\gamma^\text{opt}} \) are right half plane zeros of \( E_{\gamma^\text{opt}}M_T \).
3. By Lemma 2.2, obtain \( (H_T, F_T), (H_{R_1}, F_{R_1}) \) and \( (H_{R_2}, F_{R_2}) \) using the partitioning operator,
   \[
   H_T + F_T = \Phi(R, M_T\theta_T, M_T),
   \]
   \[
   H_{R_1} + F_{R_1} = \Phi(R, M_\theta_{\gamma^\text{opt}}),
   \]
   \[
   H_{R_2} + F_{R_2} = \Phi(e^{*T}RF_{\gamma^\text{opt}}L, \theta_{\gamma^\text{opt}}).
   \]
Then, the optimal controller has the form,
\[
\hat{C}_{\gamma^\text{opt}} = \frac{H_T + F_T}{H_{\gamma^\text{opt}} + F_{\gamma^\text{opt}}} 
\]
(16)
where \( H_T, H_{\gamma^\text{opt}} = H_{R_1} + H_{R_2} \) are TDS and \( F_T \), \( F_{\gamma^\text{opt}} = F_{R_1} + F_{R_2} \) are FIR filters. The controller has no unstable pole-zero cancellations.

#### 3.2.2. Controller Structure of FI Plants

After the data transformation is done shown as shown in (Gümüşsoy and Özbay, 2004) \( \hat{C}_{\gamma^\text{opt}}, E_{\gamma^\text{opt}}, F_{\gamma^\text{opt}} \) and \( L \) can be found as in IF plant case. We can write the inverse of the optimal controller similar to (15):
\[
\hat{C}_{\gamma^\text{opt}}^{-1} = \frac{K_{\gamma^\text{opt}} \{R/M_T \}}{R + TF_{\gamma^\text{opt}}L} 
\]
(17)
where \( K_{\gamma^\text{opt}} = E_{\gamma^\text{opt}}F_{\gamma^\text{opt}}M_TL \). Similar to IF plant case, we can obtain a reliable controller structure:

1. Do the necessary cancellations in \( K_{\gamma^\text{opt}} \).
2. Partition, \( K_{\gamma^\text{opt}} \) as, \( K_{\gamma^\text{opt}} = \theta_{\gamma^\text{opt}}\theta_R \) where \( \theta_{\gamma^\text{opt}} \) is a bi-proper transfer function. The zeros of \( \theta_{\gamma^\text{opt}} \) are unstable zeros of \( E_{\gamma^\text{opt}}M_T \).
3. By Lemma 2.2, obtain \( (H_R, F_R), (H_{T_1}, F_{T_1}) \) and \( (H_{T_2}, F_{T_2}) \) using the partitioning operator,
   \[
   H_R + F_R = \Phi(RM_T, M_T),
   \]
   \[
   H_{T_1} + F_{T_1} = \Phi(T, M_T\theta_R),
   \]
   \[
   H_{T_2} + F_{T_2} = \Phi(TF_{\gamma^\text{opt}}L, \theta_{\gamma^\text{opt}}).
   \]
Then, the optimal controller has the form,
\[
\hat{C}_{\gamma^\text{opt}} = \frac{H_R + F_R}{H_{\gamma^\text{opt}} + F_{\gamma^\text{opt}}} 
\]
(18)
where \( H_R, H_{\gamma^\text{opt}} = H_{T_1} + H_{T_2} \) are TDS and \( F_R, F_{\gamma^\text{opt}} = F_{T_1} + F_{T_2} \) are FIR filters. The controller has no unstable pole-zero cancellations. Note that the optimal controller is dual case of IF plants, \( R \) and \( T \) are interchanged with \( h_1 = T_1 = 0 \).

#### 3.2.3. Controller Structure of FF Plants

Structure of FF plants is similar to that of IF plants. We can calculate \( \gamma_{\text{opt}}, E_{\gamma_{\text{opt}}}, F_{\gamma_{\text{opt}}}, L \) by the method in (Toker and Özbay, 1995; Foias et al., 1996) and write optimal controller as:
\[
\hat{C}_{\gamma_{\text{opt}}} = \frac{K_{\gamma_{\text{opt}}} \{e^{1/2}/M_T \}}{H_R + e^{1/2}RF_{\gamma_{\text{opt}}}L} 
\]
(19)
where \( K_{\gamma_{\text{opt}}} = E_{\gamma_{\text{opt}}}F_{\gamma_{\text{opt}}}M_TL \). The optimal \( \mathcal{H}^\infty \) controller structure can be found by following similar steps as in IF plants. The controller structure will be the same as in (16). Note that when \( h_1 = T_1 = 0 \), since \( \tilde{m}_n \) in (14) is finite dimensional, it possible to cancel the zeros of \( \theta_{\gamma_{\text{opt}}} \) with denominator.

### 4. EXAMPLE

We consider IF plant (7) and weights as \( W_1(s) = \frac{2s+2}{10s+1} \) and \( W_2(s) = 0.2(s + 1.1) \). After the plant is factorized as (13), the optimal \( \mathcal{H}^\infty \) cost for two block problem (2) is \( \gamma_{\text{opt}} = 0.7203 \). The impulse responses of \( F_T \) and \( F_{\gamma_{\text{opt}}} \), of the controller (16), are FIR as in Figures 1 and 2, respectively.

![ impulse response of F_T ](ROCND06, Toulouse, France, July 5-7, 2006)
where $A_i \in \mathbb{R}^{n \times n}$, $b_j \in \mathbb{R}^{n \times 1}$, $c_k \in \mathbb{R}^{1 \times n}$ and $d \in \mathbb{R}$. Define $x(t) := [x_1(t), \ldots, x_n(t)]^T$. The time-delays, $\{h_{A,i}\}_{i=1}^n$, $\{h_{b,i}\}_{i=1}^n$, $\{h_{c,i}\}_{i=1}^n$ are nonnegative rational numbers with ascending ordering respectively and $h_d \geq 0$. Therefore, we can design an optimal $H^\infty$ controller for the plant (20) if there are no imaginary axis poles or zeros (or the weights are chosen in such a way that certain factorizations in (Foias et al., 1996) can be done).

In general to see the plant type (IF, FI, FF), the transfer function should be obtained first, then using $R$ and $T$, one can decide the plant type by Corollary 2.1 and 2.2. The optimal $H^\infty$ controller can be found by factorization of the plant and elimination of unstable pole-zero cancellations.
